We will first begin exploration of our categorical features, looking for things such as: variability within each feature (how many unique values each column takes) and redundancy (do two or more features measure/record the same thing?).

In [19]: # Again, with 'RESTAURANT_PERMIT_NUMBER', we have many unique values and thus high variability. Similarly to
# 'RESTAURANT_LOCATION', it's possible we will encounter a new, unseen value in our test set. Thus, we will drop
# this feature as well.

Do certain restaurant types have higher percentages of C grades or below? Let's find out!

So certain restaurant types have higher percentages of C grades or below. Let's find out.

```
In [23]: # First, let's drop restaurant types with low counts - this ensure that we don't get high percentages due to
# low counts. We will require a minimum count of 50
percent_experiment = explore.groupby("RESTAURANT_CATEGORY").filter(lambda x: len(x) >= 50)
```

```
In [24]: percent_experiment.head()
```

```

```

The percentage of restaurant type Restaurant that scored an inspection grade of C or below is 18.53599352925317%
The percentage of restaurant type Pantry that scored an inspection grade of C or below is 21.27659574468085%
The percentage of restaurant type Bar / Tavern that scored an inspection grade of C or below is 12.666311868014901%
The percentage of restaurant type Special Kitchen that scored an inspection grade of C or below is 14.718614718614718%
The percentage of restaurant type Meat/Poultry/Seafood that scored an inspection grade of C or below is 16.964285714285715%
The percentage of restaurant type Snack Bar that scored an inspection grade of C or below is 14.785992217898833%
The percentage of restaurant type Portable Unit that scored an inspection grade of C or below is 22.0125786163522%
The percentage of restaurant type Food Trucks / Mobile Vendor that scored an inspection grade of C or below is 18.42105263157895%
The percentage of restaurant type Buffet that scored an inspection grade of C or below is 15.591397849462366%
The percentage of restaurant type Caterer that scored an inspection grade of C or below is 14.814814814814815%

The percentage of restaurant type Banquet Kitchen that scored an inspection grade of C or below is 10.0%
The percentage of restaurant type Kitchen Bakery that scored an inspection grade of C or below is 10.0%
The average of percentages is 15.815636475413044, and the std is 13.717429221715406

With all restaurant types of count ≥ 50 , we can see that the average percentage that score a grade C or below is $\sim 15.82\%$, with a standard deviation of ~ 13.72 . The restaurant type with the highest percentage is Portable Unit with a percentage 22.01%, and the restaurant types with the lowest percentages are Banquet Kitchen and Kitchen Bakery, both with percentages of 10.00%.

We can see there exists restaurant types that have greater percentages of C grades or below, however not to a disproportionate or unexpected extent. I.e., since the restaurant types with the highest and lowest percentages are within 1 standard deviation from the mean, there is no reason to assume these are 'outlier' restaurant types.

Another question we can ask is, which restaurant types have the greatest percentages of all C grades or below? Let's find out!

```
In [28]: c_below_count = explore[explore['NEXT_INSPECTION_GRADE_C_OR_BELOW'] == '1'].shape[0]

for types in rest_type:
    # gets subset of explore df whose 'RESTAURANT_TYPE' is 'types'
    rest_subset = explore[explore['RESTAURANT_CATEGORY'] == types].copy()
    # get number of restaurants of the specific type that scored a grade c or below
    rest_c_count = rest_subset[rest_subset['NEXT_INSPECTION_GRADE_C_OR_BELOW'] == '1'].shape[0]
    print('Restaurant category {} scored {}% of all inspections grades C or below'
          .format(types, 100*rest_c_count/c_below_count))
```

Restaurant category Restaurant scored 65.10416666666667% of all inspections grades C or below
Restaurant category Pantry scored 1.4204545454545454% of all inspections grades C or below
Restaurant category Bar / Tavern scored 11.268939393939394% of all inspections grades C or below
Restaurant category Special Kitchen scored 6.4393939393939394% of all inspections grades C or below
Restaurant category Meat/Poultry/Seafood scored 0.8996212121212122% of all inspections grades C or below
Restaurant category Snack Bar scored 7.196969696969697% of all inspections grades C or below
Restaurant category Portable Unit scored 1.6571969696969697% of all inspections grades C or below
Restaurant category Food Trucks / Mobile Vendor scored 0.6628787878787878% of all inspections grades C or below
Restaurant category Buffet scored 1.3731060606060606% of all inspections grades C or below
Restaurant category Caterer scored 0.3787878787878788% of all inspections grades C or below
Restaurant category Banquet Kitchen scored 0.23674242424242425% of all inspections grades C or below
Restaurant category Kitchen Bakery scored 0.23674242424242425% of all inspections grades C or below

We can see that restaurant types Restaurant and Bar / Tavern collectively account for almost 78% of all inspection grades C or below. However, we can also see that they account for the vast majority of the dataset - i.e., there are vastly more instances with restaurant type 'Restaurant' or 'Bar / Tavern'. Thus, rather than these high percentages suggesting a relationship between restaurant type and inspection grade, it could instead reflect a type imbalance in our categorical feature 'RESTAURANT_CATEGORY'.

Additionally, it is possible we will also encounter unseen restaurant_category types in our testing data

Therefore, we will simply drop this feature as well.

```
In [29]: explore.drop('RESTAURANT_CATEGORY', axis = 1, inplace = True)
```

Next, let's look at our location features, such as ADDRESS, CITY, STATE, ZIP, and LAT_LONG_RAW

```
In [30]: # We can see that our address feature, similar to the past few categorical features, is highly variable. Thus, we
# drop this feature.

explore['ADDRESS'].value_counts()

Due to high variability, all location-related features were dropped. Though it is possible to resolve high-cardinality/high amount of unique values by using an 'other' mapping if a certain value doesn't occur enough times, for this particular dataset, location-related info seems to be unimportant if not irrelevant and redundant. Thus, all such features will be dropped.

We will now explore the remaining categorical features

Does a restaurant's current inspection grade play a role in determining its next inspection grade? Let's find out.

```

```

```

We can see that restaurants whose current grade is 'C' or 'X' have significantly greater percentages of grade C or below, with percentages of 25.7% and 38.7%, respectively. Otherwise, the percentages are quite uniform (ignoring the grade types with counts less than 50). Thus, we will incorporate three new features - 'CURRENT_GRADE_X' that has value 1 if current grade is X and 0 otherwise, 'CURRENT_GRADE_C' with the same logic, and 'CURRENT_GRADE_OTHER' that returns 1 if current grade is anything else and 0 otherwise

```
In [42]: # create three new features

explore['CURRENT_GRADE_C'] = explore['CURRENT_GRADE'].apply(lambda x: 1 if x == 'C' else 0)
explore['CURRENT_GRADE_X'] = explore['CURRENT_GRADE'].apply(lambda x: 1 if x == 'X' else 0)
explore['CURRENT_GRADE_OTHER'] = explore['CURRENT_GRADE'].apply(lambda x: 1 if x not in ['C', 'X'] else 0)
```

```

Are time of day and next inspection grade related? Let's find out!

First, we want to create a new column 'hour' that will contain what hour of the day an inspection was performed. This will be extracted from our 'INSPECTION_TIME' feature.

In [47]:

```
# First, we must extract the hour of day by converting 'INSPECTION_TIME' into a datetime object so that we can use
# pandas's built-in dt.hour method

explore['hour'] = pd.to_datetime(explore['INSPECTION_TIME'], errors = 'coerce').dt.hour
```

Since some of our 'hour' values are null, we will impute using mode to avoid conversion errors. We are going with mode since we will assume the most likely time to receive an inspection is whatever time inspections occur the most

In [48]:

```
# fill an na entries of 'hour' with the current mode of 'hour'
explore['hour'].fillna(explore['hour'].mode(), inplace = True)
```

Next, we will create one last feature called 'TimeOfDay' which categorizes inspection times into 'Morning', 'Afternoon', and 'Evening' using our newly created 'hour' feature. Any inspections performed on hours [0, 11] will be considered Morning, (12, 17] considered Afternoon, and (17, 24] considered Evening.

In [49]:

```
# create cut-offs for inspection times
bins = [0,11,17,25]
# create corresponding labels
labels = ['Morning','Afternoon','Evening']
# create new feature using bins and labels
explore['TimeOfDay'] = pd.cut(explore['hour'], bins = bins, labels = labels, include_lowest = True)
```

In [50]:

```
# now see if a certain time of day has a greater percentage of grades C or below
explore.groupby(['TimeOfDay', 'NEXT_INSPECTION_GRADE_C_OR_BELOW']).agg({'NEXT_INSPECTION_GRADE_C_OR_BELOW': 'count'})
```

Out[50]:

	NEXT_INSPECTION_GRADE_C_OR_BELOW
TimeOfDay	NEXT_INSPECTION_GRADE_C_OR_BELOW
Morning	0

	1	672
Afternoon	0	6407
	1	1316
Evening	0	468
	1	98

Looking at the percentage of grade C or below for each TimeOfDay, we can see that the percentages are 16.5%, 17.04%, and 17.31% for Morning, Afternoon, and Evening, respectively. Since none of the percentages are disproportionately big or small relative to the others, we will simply drop the features 'INSPECTION_TIME', 'hour', and 'TimeOfDay', as they do not seem to provide actionable statistical insight

```
In [51]: # drop features
explore.drop(['INSPECTION_TIME', 'hour', 'TimeOfDay'], axis = 1, inplace = True)
```

Now let's check to see if there's any relation between 'INSPECTION_TYPE' and inspection grade

```
In [52]: explore.groupby(['INSPECTION_TYPE', 'NEXT_INSPECTION_GRADE_C_OR_BELOW'])\
.agg({'NEXT_INSPECTION_GRADE_C_OR_BELOW': 'count'})
```

```
Out[52]:
```

Routine Inspection	0	9654
	1	1962
Routine Inspection by Cat	0	1
Routine Non-Inspection	1	2
San Dimas High School Football Rules	0	1

Looking at only 'Routine' Inspection and 'Re-inspection', we can see that the percentages of grade C and below are 16.9% and 18.5%, respectively. We will therefore create two new columns - one to indicate if the inspection type is a re-inspection, and one to indicate otherwise. These will be named 'RE-INSPEC' and 'OTHER-INSPEC' otherwise.

```
In [53]: # create 'RE-INSPEC' column
explore['RE-INSPEC'] = explore['INSPECTION_TYPE'].apply(lambda x: 1 if x == 'Re-inspection' else 0)
# create 'RE-OTHER' column
explore['OTHER-INSPEC'] = explore['INSPECTION_TYPE'].apply(lambda x: 1 if x != 'Re-inspection' else 0)
```

```
In [54]: # check to see that new features are behaving as expected

Is there a relation between how many types (Non-Major, Major, Critical) of violations a location received and a grade of C or below? Let's find out!

We will start off with creating new columns that contain the counts of each type for every location

```
In [61]: # first create columns that return 1 if violation is type 'critical', 0 otherwise
explore['first_critical'] = explore['FIRST_VIOLATION_TYPE'].apply(lambda x: 1 if x == 'Critical' else 0)
explore['second_critical'] = explore['SECOND_VIOLATION_TYPE'].apply(lambda x: 1 if x == 'Critical' else 0)
explore['third_critical'] = explore['THIRD_VIOLATION_TYPE'].apply(lambda x: 1 if x == 'Critical' else 0)
```

```

In [62]: # then create a column that returns the count of type 'critical' by summing along our previously created columns
explore['CRITICAL_COUNT'] = explore[['first_critical', 'second_critical', 'third_critical']].sum(axis = 1)

In [63]: # first create columns that return 1 if violation is type 'major', 0 otherwise
explore['first_major'] = explore['FIRST_VIOLATION_TYPE'].apply(lambda x: 1 if x == 'Major' else 0)
explore['second_major'] = explore['SECOND_VIOLATION_TYPE'].apply(lambda x: 1 if x == 'Major' else 0)
explore['third_major'] = explore['THIRD_VIOLATION_TYPE'].apply(lambda x: 1 if x == 'Major' else 0)

In [64]: # then create a column that returns the count of type 'major' by summing along our previously created columns
explore['MAJOR_COUNT'] = explore[['first_major', 'second_major', 'third_major']].sum(axis = 1)

In [65]: # first create columns that return 1 if violation is type 'non-major', 0 otherwise
explore['first_non-major'] = explore['FIRST_VIOLATION_TYPE'].apply(lambda x: 1 if x == 'Non-Major' else 0)
explore['second_non-major'] = explore['SECOND_VIOLATION_TYPE'].apply(lambda x: 1 if x == 'Non-Major' else 0)
explore['third_non-major'] = explore['THIRD_VIOLATION_TYPE'].apply(lambda x: 1 if x == 'Non-Major' else 0)

In [66]: # then create a column that returns the count of type 'non-major' by summing along our previously created columns
explore['NON-MAJOR_COUNT'] = explore[['first_non-major', 'second_non-major', 'third_non-major']].sum(axis = 1)

In [67]: # then drop the binary-valued columns since we no longer need them anymore
explore.drop(['first_non-major', 'second_non-major', 'third_non-major',
              'first_major', 'second_major', 'third_major',
              'first_critical', 'second_critical', 'third_critical'], axis = 1, inplace = True)

In [68]: # lastly, drop the violation_type columns as well
explore.drop(['FIRST_VIOLATION_TYPE', 'SECOND_VIOLATION_TYPE', 'THIRD_VIOLATION_TYPE'], axis = 1, inplace = True)

In [69]: # now let's check if our count columns are working as expected

Now that we've finished exploring our categorical features, we will assess the relative importance of our numerical features using random forest.

First, we will isolate the numerical features we did not create ourselves

```

In [70]: # retrieve numerical features that were not engineered ourselves
X_num_only = explore.iloc[:, [1,2,3,4,5,6]].copy()
# retrieve copy of response variable as well
y_num_only = explore['NEXT_INSPECTION_GRADE_C_OR_BELOW'].copy()

In [71]: # check to see that we got all relevant features

5   NUMBER_OF_VIOLATIONS  12375 non-null  object
dtypes: float64(3), object(3)

```

We can see that the features 'MEDIAN_EMPLOYEE_AGE', 'INSPECTION_DEMERITS', 'NUMBER_OF_VIOLATIONS' are 'object' datatypes. This is a problem since they need to be numeric features to work with our random forest model. It's possible there are non-numerical values present in these features, so to resolve this, we will use pandas to_numeric method, which converts numeric-values to numerica types, and non-numerics to NaNs. We will then resolve these NaNs by imputing.

```
In [73]: # columns that are 'object' types
obj_cols = ['MEDIAN_EMPLOYEE_AGE', 'INSPECTION_DEMERITS', 'NUMBER_OF_VIOLATIONS']
# convert each feature to numeric types. The argument errors = 'coerce' forces non-numeric into NaNs
X_num_only[obj_cols] = X_num_only[obj_cols].apply(pd.to_numeric, errors='coerce')
```

```
In [74]: # check to see that all features are now 'float64' datatypes

Now, we will impute null values with the mode for each numerical feature. We will also perform thess same transformations on our testing data later on - this ensures that when making predictions, we will not get errors related to invalid data types

```
In [75]: # columns we want to impute on
cols = ['CURRENT_DEMERITS', 'EMPLOYEE_COUNT', 'MEDIAN_EMPLOYEE_AGE',
        'MEDIAN_EMPLOYEE_TENURE', 'INSPECTION_DEMERITS', 'NUMBER_OF_VIOLATIONS']
# impute using the mode of each column

```

When we include all features, we get similar results. The top 5 most important features are 'MEDIAN_EMPLOYEE_AGE', 'MEDIAN_EMPLOYEE_TENURE', 'EMPLOYEE_COUNT', 'CURRENT_DEMERITS', and 'INSPECTION_DEMERITS'.

Now let's perform feature importance based on feature permutation. This is essentially a way of measuring how much our model depends on a particular feature to make its final predictions.

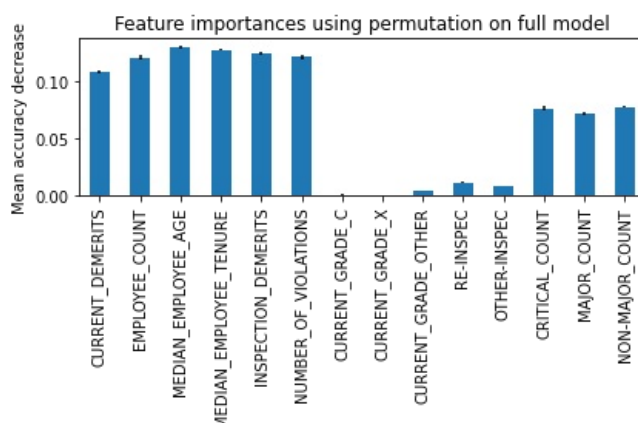

```
In [90]: from sklearn.inspection import permutation_importance

start_time = time.time()
# store results of permutation importance
result = permutation_importance(
    forest_num, X_num, y_num, n_repeats=10, random_state=42, n_jobs=-1
)
elapsed_time = time.time() - start_time
print(f"Elapsed time to compute the importances: {elapsed_time:.3f} seconds")

# final feature importances are stored
forest_importances = pd.Series(result.importances_mean, index=feature_names)
```

Elapsed time to compute the importances: 20.762 seconds

```
In [91]: # plot resultant feature importances based on feature permutation
fig, ax = plt.subplots()
forest_importances.plot.bar(yerr=result.importances_std, ax=ax)
ax.set_title("Feature importances using permutation on full model")
ax.set_ylabel("Mean accuracy decrease")
fig.tight_layout()
plt.show()
```

We can see that based on feature permutation, the features 'MEDIAN_EMPLOYEE_AGE', 'MEDIAN_EMPLOYEE_TENURE', 'EMPLOYEE_COUNT', 'CURRENT_DEMERITS', 'INSPECTION_DEMERITS', 'NUMBER_OF_VIOLATIONS', 'CRITICAL_COUNT',

'MAJOR_COUNT', and 'NON-MAJOR_COUNT' are relatively important to our model's final predictions. Thus, these are the features we will include in our final model.

```
In [195]: X_num = X_num[['MEDIAN_EMPLOYEE_AGE', 'MEDIAN_EMPLOYEE_TENURE', 'EMPLOYEE_COUNT',  
                    'CURRENT_DEMERITS', 'INSPECTION_DEMERITS', 'NUMBER_OF_VIOLATIONS',  
                    'CRITICAL_COUNT', 'MAJOR_COUNT', 'NON-MAJOR_COUNT']].copy()
```

Before testing our final model on our validation set, we will see how it performs on the training set using cross-validation.

```
In [196]: from sklearn.model_selection import cross_val_score  
  
# create RandomForestClassifier model  
final_model = RandomForestClassifier(random_state = 42)  
  
# store results of CV scores  
results = cross_val_score(final_model, X_num, y_num, scoring = 'accuracy', cv = 5, n_jobs = -1)  
  
print(results)  
print('The average CV score with 5 folds is {}'.format(np.mean(results)))  
  
[0.83046781 0.8256      0.8292      0.8284      0.8288      ]  
The average CV score with 5 folds is 0.82849356257497
```

On average, we get a cross-validation score of 82.76%. Let's also calculate other important metrics, such as precision, recall, and F1-score.

```
In [197]: # store precision results  
precision = cross_val_score(final_model, X_num, pd.to_numeric(y_num), scoring='precision',  
                             cv=5, n_jobs = -1)  
  
# store recall results  
recall = cross_val_score(final_model, X_num, pd.to_numeric(y_num), scoring='recall',  
                           cv=5, n_jobs = -1)  
  
# store f1_score results  
f1_score = cross_val_score(final_model, X_num, pd.to_numeric(y_num), scoring='f1',  
                             cv=5, n_jobs = -1)  
  
print('Our average precision score is {}, our average recall score is {}, and our average f1 score is {}'.format(  
      np.mean(precision), np.mean(recall), np.mean(f1_score)))  
  
Our average precision score is 0.28345765345765345, our average recall score is 0.008520721992538066, and our average f1 score is 0.01651058185333959
```

Unfortunately, our average recall, precision, and f1 score is very low. This is highly due to the fact that we have an unbalanced dataset, whereby there are many more locations that don't score a grade C or below than those that do. Thus, we must somehow account for this.

First, we will use the library imblearn. imblearn was created to deal with unbalanced datasets for machine learning problems, and works seamlessly with sci-kit learn. Thus, we start off with imblearn's BalancedRandomForestClassifier model with default parameters. BalancedRandomForestClassifier works by undersampling the majority class for each bootstrapping iteration, so that the majority and minority classes have equal weight. This is more effective than simply undersampling our dataset from the onset and we are able to preserve the information that comes in all our data.

```
In [198]: from imblearn.ensemble import BalancedRandomForestClassifier  
  
# create BalancedRandomForestClassifier model

```

```
print('Our average precision score is {}, our average recall score is {}, and our average f1 score is {}'.format\
      (np.mean(precision), np.mean(recall), np.mean(f1_score)))
```

Our average precision score is 0.18178215864080538, our average recall score is 0.2514077958163871, and our average f1 score is 0.2108834313465377

We can see that our average precision, recall, and F1 scores are already significantly better using imblearn's `BalancedRandomForestClassifier` model. Let's see if tuning its hyperparameters will yield better results.

We will accomplish this by performing a grid search on our hyper-parameter space.

In [199]

```
from sklearn.model_selection import GridSearchCV

# establish hyper-parameter space to search from
params = {'n_estimators': [50, 100, 300, 500],
          'max_depth': [3, 4, 7], 'max_features': ['sqrt', 5, 7, 8]}

# create new BalancedRandomForestClassifier model
new_model = BalancedRandomForestClassifier(random_state = 42)

# create grid with hyper-parameter space
grid_search = GridSearchCV(new_model, params, scoring = 'f1', n_jobs = -1)

grid_search.fit(X_num, pd.to_numeric(y_num))

cv = grid_search.cv_results_

for scores, params in sorted(zip(cv['mean_test_score'], cv['params']), reverse = True):
    print(scores, params)

We can see that the model with the best performance has hyper-parameters 'max_depth': 7, 'max_features': 7, 'n_estimators': 300. Thus, our final model will have these same hyper-parameters.

We will now train our model on the entire training set and test its performance on the validation set.

```
In [200... validation_model = BalancedRandomForestClassifier(max_depth = 7, max_features = 7, n_estimators = 300)
# fit model on training data
validation_model.fit(X_num, y_num)
```
